Abstract

Driving cycles are used to understand the driving pattern of vehicles and in estimating their emissions. Although several studies exist on driving cycles worldwide, few studies have focused on developing driving cycles for intra-city buses in heterogeneous traffic conditions. In this study, driving cycles for intra-city buses were developed using real-world GPS data collected during peak and off-peak periods in Chennai city, India. We construct candidate cycles using a k-means clustering and a one-step Markov modelling method. The cycles have different durations ranging from 400 seconds to 2800 seconds to understand the effect of duration on error. An average error for each duration of the candidate cycle was determined. We select the duration which corresponds to the least average error for developing the final driving cycle. Three different driving cycles - corresponding to morning peak hour, off-peak hour, and evening peak hour - are developed. Finally, we compare the developed cycles with the existing local and international cycles. The developed driving cycle was found to be significantly different from the existing cycles for buses.

Keywords: Driving cycle; k-means clustering; buses.

1. Introduction

A driving cycle is a plot of the speed of a vehicle over time. They are used to characterize the driving conditions under which a vehicle operates within a specified duration. Typically, the duration of the driving cycles varies from 10 minutes to 40 minutes and may be different for peak and off-peak periods. Moreover, for a particular city, several driving cycles may be developed for different road types (arterials, freeways, and local roads) and vehicle types (buses, trucks, cars, and motorcycles).

The development of real-world driving cycles involves three stages: route selection, real-world driving data collection, and driving cycle construction. Route selection requires selection of the most representative routes to capture the driving behavior of all the vehicles. Generally, data is collected on the routes carrying predominant traffic. The real-world driving data is collected every second using a GPS device mounted on the test vehicle. Finally, the data is used to develop driving cycles which represent the real-world driving conditions.

Emission testing and certification of vehicles in the laboratory are done using standard driving cycles. Accurate estimation of driving cycles would lead to better quantification of emissions from gasoline and diesel-powered motor vehicles. Also, driving cycles of electric vehicles can be used to determine their range and power consumption which decides the characteristics of the battery used.

This study uses real-world second-by-second GPS data collected from intra-city buses to develop driving cycles in heterogeneous traffic conditions. The methodology for developing driving cycles involves clustering the microtrips using k-means clustering process and cluster sequencing using one step Markov modeling process. We then compare the developed driving cycles with the existing cycles.

This paper has five sections. Section 1 provided an introduction to the paper. Section 2 presents the existing literature related to driving cycles. Section 3 explains the methodology adopted in this study. Section 4 presents the results and discussion of the findings. Finally, section 5 presents the concluding remarks.

2. Literature review

Literature review suggests several definitions of driving cycle such as “a representation of a speed-time sequenced profile developed for a specific area or city” (Hung et al., 2007) and “is a sequence of operating conditions (idle, acceleration, deceleration and cruise) developed to represent a typical driving pattern of a city” (Nesamani and Subramanian, 2011). Another definition of driving cycle being “a representative plot of driving behavior of a given city or a region and is characterized by speed and acceleration” (Kamble et al., 2009).

The driving cycles of a particular region are affected by the following factors: type of roads, geography, local enforcement of traffic rules, and the method of data collection and cycle construction. Driving cycle consists of smaller elements called microtrips (MT) which also has different definitions, though the most widely used definition is “trip between two idling periods.” The duration of driving cycles ranges from 10-40 minutes as this duration is long enough to capture the driving behaviour and is feasible in practice (Arun et al., 2017).

Due to the need for developing a driving cycle for a particular location, developing driving cycles for various locations began in 1978 in Sydney (Kent et al., 1978). Subsequently, driving cycles were developed in all the continents of the world due to an increase in the need for developing driving cycles for each region due to variations in driving behaviour. Major driving cycles include Taipei (Tzeng and Chen, 1998), Delhi (Badusha and Ghosh, 1999), Hong Kong (Tong et al., 1999), Pune (Kamble et al., 2009), Chennai (Nesamani and Subramanian, 2011), Edinburgh (Saleh et al., 2012), Singapore (Ho et al., 2014), Toronto (Amirjamshidi and Roorda, 2015), and Khon Kaen (Seedam et al., 2015). Almost all the recently developed driving cycles use similar assessment parameters such as average speed, average acceleration, and percentage idle time. Sydney driving cycle used only three parameters, i.e., average speed, rms acceleration, and percentage idle time, while the recently developed driving cycles such as Toronto and Singapore used up to 10 assessment parameters. However, while developing a driving cycle, most of the studies adopted a random selection of microtrips, and the constructed candidate cycle is then compared with target parameters to find the most representative driving cycle. Further, the developed driving cycle is compared with international standard driving cycles.

Research on driving cycles in India has been growing over the past few decades due to an increase in the number of vehicles and the need to estimate their emissions. The Indian driving cycles neglected higher speed and assumed similar behavior irrespective of heterogeneity in traffic. Kamble et al. (2009) use important parameters describing time-space profile namely percentage time spent in acceleration, deceleration, idle, cruise and creep modes. Microtrips were shortlisted for candidate cycle construction by comparing parameters of each microtrip. In another study, a driving cycle was developed for intra-city buses in Chennai (Nesamani and Subramanian, 2011). The study used 14 assessment parameters to construct a distance based driving cycle. Microtrips were selected randomly to construct a candidate cycle until it reached the target distance and then compared against the target values. The bus driving cycle on state highway, Maharashtra is another driving cycle for buses in highway driving. In this study, assessment

parameters were calculated for each microtrip and compared with assessment parameters of the population (target statistics). If the difference was greater than 5%, then those microtrips were rejected and the rest are used for constructing the candidate cycle.

3. Methodology

3.1. Data collection

Second-by-second data was collected from intra-city buses on several different routes in Chennai city using hand-held GPS units. The data were collected on different days (including weekdays and weekends) and included peak and off-peak periods. The collected data included multiple to and fro trips of the same buses for an entire day.

3.2. Data processing

We checked the collected data for accuracy, continuity, and corrected anomalies (for example, data when the bus is idle in the depot). The cleaned data was used to derive other parameters such as acceleration and deceleration for assessing the candidate cycle. The speed data related to an individual trip from the origin to the destination was separated for further analysis.

3.3. Driving cycle construction

Fig 1. shows the flow chart of the methodology adopted for driving cycle construction. The four main steps were: generation of microtrips, categorization of microtrips using k-means clustering, determination of assessment parameters, and construction of the candidate cycle. From the second-by-second speed data, microtrips were generated assuming a microtrip to start when speed increases from zero and end at the next start from speed zero. Thus, every microtrip has an idling period in the end. Microtrips are then categorized into different classes using k-means clustering. An elbow plot helped determine the optimal number of clusters. The closeness of a candidate cycle to the whole data is compared using the set of assessment parameters shown in Table 1. We select candidate cycles by comparing 'test statistics' (assessment parameters of the candidate cycle) with population parameters also known as 'target statistics.'

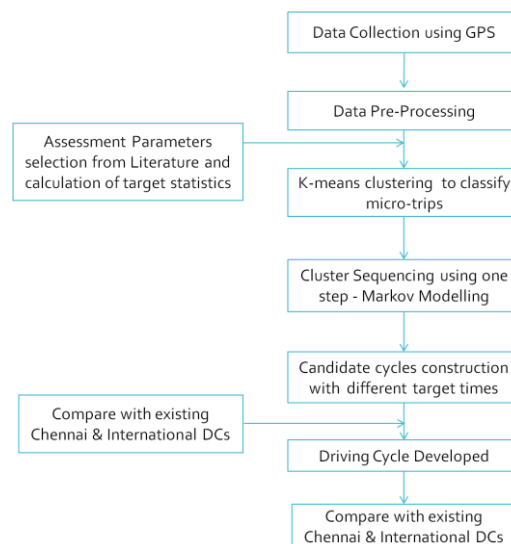

Figure 1. Flowchart of methodology.

Table 1. Selected assessment parameters.

| S. No. | Assessment parameter | Units |
|--------|---|--------------------|
| 1 | Average speed (V) for entire trip | km h ⁻¹ |
| 2 | Average running speed (V _r) | km h ⁻¹ |
| 3 | Average acceleration (a) of all acceleration phases | m s ⁻² |
| 4 | Average deceleration (d) of all deceleration phases | m s ⁻² |
| 5 | Percentage of time spent in idle mode (P _i) (speed=0) | % |
| 6 | Percentage of time spent in acceleration mode (P _a) (acceleration >= 0.1 m/s ²) | % |
| 7 | Percentage of time spent in deceleration mode (P _d) (acceleration <= -0.1 m/s ²) | % |
| 8 | Percentage of time spent in creeping mode (P _{cr}) (-0.1m/s ² < acceleration < 0.1 m/s ² , speed < 5 kmph) | % |
| 9 | Percentage of time spent in cruise mode (P _c) (-0.1 m/s ² < acceleration < 0.1 m/s ² , speed > 5 kmph) | % |
| 10 | Average no. of acceleration – deceleration phases (vice versa) in one driving period (P _{ad}) | % |
| 11 | Root mean square acceleration (a _{rms}) $a_{rms} = \sqrt{\sum acceleration^2}$ | m s ⁻² |
| 12 | Positive acceleration kinetic energy (PKE) | m s ⁻² |

The construction of the candidate cycle involves the following steps. (1) Initial microtrip of the whole data is used to start every candidate cycle. Second microtrip is then selected based on one-chain Markov modeling, and the process continues. (2) For Markov chain modeling, we construct a transition matrix based on one step succession. Here, we calculate probability of a specific cluster succeeding another cluster. Table 2 provides a sample of a transition matrix. (3) After construction of the transition matrix, it is cumulated along the row as shown in Table 3. A random number between 0 and 1 is selected and based on where it falls, i.e., between which columns for a particular row, we choose the succeeding cluster. (4) We repeat this process until the required time for candidate cycle is achieved.

In this study, the duration of the candidate cycle is varied from 400 seconds to 2800 seconds in increments of 200 seconds. For every duration, the best candidate cycle with least total mean is chosen as the driving cycle. Error of candidate cycle is calculated by the formula given below:

$$S_i = \left(\frac{|P_i - P_i|}{P_i} \right) \quad (1)$$

P_i = Target parameter i of entire collected data

p_i = Target parameter i of the candidate cycle

The mean error is calculated using the following equation:

$$ME = \sum_{j=1}^n S_i / (n) \tag{2}$$

n = No. of assessment parameters

S_i = Relative error of the i^{th} parameter

Through this method, dynamic driving cycles are constructed which helps when there is a time constraint in the duration of driving cycle.

4. Results and discussion

4.1 Driving cycle for morning peak hour

Figure 2 shows the developed driving cycle for the morning peak hour. Figure .3 shows the variation in the errors with different durations of the candidate driving cycles. The error is about 20% for a driving cycle of duration 400 seconds and decreases drastically with increase in duration up to 1200 seconds. The least average error of the candidate cycles is for 1200 seconds. Subsequently, the error value remains constant at about 10%.

Figure 2 Driving cycle for morning peak hour

Figure 3 Average total error of candidate cycle versus approximate duration of the cycle

The assessment parameters used for determining the candidate cycles and the microtrips comprising the developed cycle (Figure 2) are shown in Tables 4 and 5, respectively. As seen from Table 4, the total duration of the driving cycle is 1271 seconds with an average speed of 23 km/h and average running speed of 30.82 km/h. The other parameters of the developed driving cycle were very similar to the target statistics. In total, 21 microtrips are comprising the developed driving cycle for morning peak hour.

4.2 Driving cycle for evening peak hours

Figure 4 shows the driving cycle for evening peak hour. Figure 5 shows the variation in the average error of the candidate cycles for different durations. The average error is about 30% for driving cycles of duration 600 seconds and decreases continuously with increase in the duration of the cycle. The lowest error is about 13% corresponding to a duration of 2000 seconds. The developed driving cycle has a duration of 2055 seconds.

Figure 4 Driving cycle for evening peak hour

Figure 5 Average total error of driving cycle versus approximate duration of cycle

Table 6 provides the assessment parameters and the observed values of the parameters for the developed evening peak hour driving cycle. The average speed of the cycle is about 17 km/h which is significantly lower than the morning peak hour cycle. The assessment parameters values for the developed cycle match well with the target statistics. Table 7 lists the assessment parameter values for the microtrips comprising the evening peak hour driving cycle. The number of microtrips is comparatively higher with many of them of short duration. The assessment parameters also vary considerably among the microtrips.

Table 6 Assessment parameters for evening peak hours.

4.3 Driving cycle for off-peak hours

Figure 6 shows the driving cycle for off-peak hours. The number of microtrips are lower relative to the peak hour cycles, and we observe higher speeds. The duration of the microtrips comprising the driving cycle is also higher. Four microtrips of duration above 200 seconds dominate the driving cycle. Overall, there are 12 microtrips in the developed

driving cycle with a total duration of 1649 seconds. Figure 7 plots the variation in the average error of candidate cycles with duration. In this case, the error ranges from 2% for 400 seconds to 0.5% for 2800 seconds.

Figure 6 Driving cycle for off-peak hours.

Figure 7 Average total error of driving cycle versus approximate duration of cycle.

Table 8 lists the assessment parameters for the development of the off-peak hour driving cycle. The parameter values of the developed driving cycle match well with the target statistics for off-peak hours. The parameters of the 12 microtrips comprising the off-peak hour driving cycle are given in Table 9. Although the duration of the microtrips varies widely, four microtrips of more than 200 seconds duration almost cover the entire cycle. Also, the average speed of the off-peak hour driving cycle is higher relative to the peak hour cycles.

4.4 Comparison with existing driving cycles

Table 10 provides a comparison of developed Chennai bus driving cycles to existing driving cycles. The average speed and average running speed of the developed cycle was lower than the Hong Kong and the FTP driving cycles. The average acceleration was also lower than all the existing driving cycles. This indicates the extent of congested traffic conditions prevalent on the arterial roads of Chennai city. Other assessment parameters such as root mean square acceleration and PKE also show a significant difference to the existing driving cycles. Since these cycles were developed primarily for passenger cars, a comparison with the existing driving cycles for buses is required.

Table 10 Comparison of the overall driving cycle with international cycles.

| Parameter | Chennai | HK | FTP 72 | FTP 75 | LA 92 | ECE 15 | 10 Mode | 10 - 15 Mode |
|--|---------|-------|--------|--------|-------|--------|---------|--------------|
| Average speed (km/h) | 22.29 | 25 | 31.5 | 34.1 | 39.6 | 18.4 | 17.6 | 22.7 |
| Average running speed (km/h) | 29.00 | 30.4 | 38.3 | 41.6 | 46.7 | 26.5 | 24.1 | 33.1 |
| Average acceleration (m/s ²) | 0.35 | 0.595 | 0.597 | 0.607 | 0.673 | 0.642 | 0.673 | 0.569 |
| Average deceleration (m/s ²) | 0.57 | 0.593 | 0.695 | 0.7 | 0.754 | 0.748 | 0.654 | 0.647 |
| Percent acceleration (m/s ²) | 34.65 | 34.5 | 32.8 | 32.4 | 38.2 | 21.5 | 24.3 | 25.2 |
| Percent deceleration (m/s ²) | 24.60 | 34.2 | 28.3 | 28.2 | 34.1 | 18.5 | 25 | 22.1 |
| Percent idle (%) | 17.06 | 17.8 | 17.6 | 17.9 | 15.2 | 30.8 | 27.2 | 31.4 |
| Percent cruise (%) | 23.15 | 12 | 20.9 | 21.2 | 12.2 | 29.2 | 23.5 | 21.4 |
| Percent creep (%) | 0.53 | 1.5 | 0.4 | 0.3 | 0.3 | - | - | - |
| RMS acceleration (m/s ²) | 0.48 | 0.73 | 0.74 | 0.76 | 0.846 | 0.661 | 0.692 | 0.612 |
| PKE (m/s ²) | 0.30 | 0.39 | 0.38 | 0.384 | 0.409 | 0.565 | 0.577 | 0.427 |

Table 11 compares the developed driving cycles with the existing bus driving cycles in India as well as abroad. The Central Business District Cycle (CBDC) and the Dutch Urban Bus Driving Cycle (DUBDC) are given in Pelkmans et al. (2001), and the Delhi Bus Driving Cycle (DBDC) is given by ARAI (2007). Further, Maurya and Bokare (2012) present a driving cycle for buses on highways (SHM driving cycle). The average speed and average running speed are similar for all the urban driving cycles. However, it is higher for the SHM cycles. The DBDC has

the lowest average speed in contrast to the SHM cycles. Idling periods are higher in the CBDC and DUBDC cycles, whereas cruising time is highest in the Pune driving cycle.

Table 11 Comparison of the developed driving cycle with existing bus driving cycles and Pune driving cycle.

| Parameter | Morning peak | Evening peak | Off-peak | CBDC | DUBDC | DBDC | Pune | SHM Morning Peak | SHM Off-Peak | SHM Evening Peak |
|--|--------------|--------------|----------|-------|-------|-------|-------|------------------|--------------|------------------|
| Average speed (km/h) | 23.03 | 22.29 | 24.31 | 20.23 | 20.96 | 18 | 19.55 | 38.45 | 44.6 | 31.1 |
| Average running speed (km/h) | 30.82 | 29.00 | 30.7 | 27 | 28.29 | 23 | - | 40.5 | 46.84 | 34.31 |
| Average acceleration (m/s ²) | 0.36 | 0.35 | 0.38 | 0.89 | 0.57 | 0.4 | 3.72 | 0.28 | 0.32 | 0.29 |
| Average deceleration (m/s ²) | 0.66 | 0.57 | 0.58 | 1.22 | 0.69 | 0.49 | 4.57 | 0.37 | 0.32 | 0.58 |
| Percent acceleration (%) | 36.64 | 34.65 | 35.72 | 30.61 | 40 | 38.78 | 14.18 | 25.98 | 28.31 | 36.66 |
| Percent deceleration (%) | 23.48 | 24.60 | 25.05 | 14.29 | 33.1 | 32.65 | 11.48 | 21.54 | 15.46 | 15.53 |
| Percent idle (%) | 14.19 | 17.06 | 18.13 | 22.45 | 22.57 | 20.41 | 18.09 | 5.18 | 4.22 | 9.41 |
| Percent cruise (%) | 25.28 | 23.15 | 20.8 | 32.65 | 4.33 | 8.16 | 56.25 | 46.62 | 50.42 | 37.06 |
| Percent creep (%) | 0.34 | 0.53 | 0.3 | - | - | - | - | - | - | - |
| PKE (m/s ²) | 0.32 | 0.30 | 0.31 | 0.2 | 0.53 | - | - | 0.45 | 0.66 | 0.56 |

5. Conclusions

This study developed driving cycles for intra-city buses of Chennai in peak hours (morning and evening) and off-peak hours using k-means clustering and one-step Markov chain modelling method. The candidate cycles were developed based on twelve assessment parameters with eleven parameters as used in existing studies. Percentage time in changing from acceleration to deceleration modes is added to the list based on past literature. The candidate cycles were developed by dividing the real-world speed-time data into microtrips and classifying them using k-means clustering. Then, one-step Markov chain modeling is used to sequence them into a candidate cycle of a particular duration. This study also attempted to understand the effect of duration of the driving cycle on its representativeness of the real-world conditions. Thus, candidate driving cycles of time periods ranging from 400 seconds to 2800 seconds at an interval of 200 seconds were developed. The developed driving cycles were compared with the existing international and Indian driving cycles such as the Hong Kong, US, European, Japanese, Pune, and Delhi cycles.
